Foreword/Acknowledgments

This report was prepared by the Acoustics and Aerospace Technologies Branch of the Aerospace, Transportation, and Advanced Systems Laboratory (ATASL) of Georgia Tech Research Institute (GTRI) for NASA Langley Research Center, Hampton, Virginia, under Grant NAG1-1734.

Mr. Mike Jones was the Project Manager for NASA Langley Research Center. GTRI's Project Director was Dr. K.K. Ahuja.

This work was carried out to obtain data for validation of computational codes being developed by Dr. C. K. W. Tam of Florida State University. The authors would like to thank Dr. Tam for suggesting the experiment reported here. The authors would also like to thank Mr. Tony Parrott and Mr. Mike Jones of NASA Langley Research Center for their support of this work.

Note that this report is one of five separate volumes prepared to document the work conducted by GTRI under NASA Grant NAG1-1734. The GTRI report numbers, authors, and titles of each report are listed in the table below:

Executive Summary

The objective of the study reported here was to acquire detailed acoustic data and limited and flow visualization data for numerical validation a new model of sound absorption by a very narrow rectangular slit backed by a cavity. The sound absorption model is being developed by Dr. C. K. W. Tam of Florida State University. This report documents normal incidence impedance measurements of a singular rectangular slit orifice with no mean flow. All impedance measurements are made within a 1.12 inch (28.5 mm) diameter impedance tube using the two-microphone method for several frequencies in the range 1000 –6000Hz and incident sound pressure levels in the range 130 – 150 dB. In the interest of leaving the analysis of the data to the developers of more advanced analytical and computational models of sound absorption by narrow slits, we have refrained from giving our own explanations of the observed results, although many of the observed results can be explained using the classical explanations of sound absorption by orifices.

1.0 Introduction

The state of computational aeroacoustics has progressed to the point where direct numerical simulation (DNS) of acoustic liner performance is imminent. Dr. Chris Tam of Florida State University has developed a DNS aeroacoustics code to examine sound absorbing properties of orifices with a backing cavity¹. In an effort to help validate his model, GTRI has conducted an experiment that measures the impedance of a slit-orifice with a backing cavity for several frequencies and incident sound pressure levels. Furthermore, flow visualization using a Particle Imaging Velocimeter was obtained of the acoustic interaction with the slit-orifice cavity which allowed for qualitative assessment of the slit acoustic behavior. This report documents these impedance and flow visualization experiments.

2.0 Experimental Approach and Facilities

The numerical model of Dr. Tam¹ is two-dimensional, and employed a 0.032 inch (0.8 mm) wide slit covering a rectangular cavity whose depth was equal to the quarter-wavelength of a 3000 Hz acoustic wave (2.88 cm). Experiments conducted at GTRI used a normal incidence impedance tube with a circular cross section. With these differences noted, Figure 1 shows the set-up of the GTRI experiments. The controlled variables in this experiment were acoustic frequency and amplitude. Table I shows the test conditions covered in the present study. It should be noted that 5000 Hz was not examined as a high enough amplitude could not be attained with our driver-impedance tube system. For each case, the reflection coefficient, absorption coefficient, and acoustic impedance were measured.

Frequency [Hz]	Incident Amplitude [dB]
1000	130, 150
2000	130, 150
3000	130, 150
4000	130, 150
6000	130, 150

Table I. Test conditions for slit-orifice with backing cavity.

Investigation of the fluid motion caused by the impinging sound wave near the slit-orifice was performed using an acrylic tube of nominally the same dimensions as the steel impedance tube shown in Figure 1. Using a Particle Image Velocimeter (PIV), a laser sheet was introduced across the width of the slit-orifice and cavity, illuminating incense smoke that was allowed to fill the tube before the driver was turned on. For 1000 Hz and 3000 Hz, images were obtained which allow visualization of the instantaneous fluid in motion at both 130 dB and 150 dB. This allowed visualization of vortex formation downstream of the slit when it took place.

2.1 Normal Incidence Impedance Tube

The normal incidence acoustic impedance was measured in a steel impedance tube that operates using the Two Microphone Method as originally described by Chung and Blaser². The general specifications of the impedance tube are detailed in reference 3. The tube's inner diameter is 1.12 inches (28.5 mm) and an orifice plate containing the slit-orifice was placed between flanges on the impedance tube at the measurement reference plane. A high intensity acoustic driver was used to produce sinusoidal incident acoustic waves upon the slit orifice. Figure 2 shows the actual slit-orifice plate used in the experiments.

2.2 Normal Incidence Acoustic Flow Visualization Apparatus

GTRI uses a state-of-the-art TSI Power View PIV system. This system incorporates a high resolution, 30 frames per second CCD camera, dual-YAG lasers, and a Laser Pulse Light Arm for delivery of the laser beam. A clear acrylic tube was attached to an acoustic driver at one end and a slit-orifice with backing cavity at the other end. Dimensions of this apparatus were chosen to simulate the steel impedance tube configuration alluded to above. Indeed the same acoustic driver model was used and the same orifice plate was used. Driver voltages used in the impedance tube experiments were input to simulate the same conditions for the flow visualization apparatus. Figure 3 shows a schematic of this apparatus and its "field of view."

3.0 Data Acquisition and Reduction

Acoustic impedance was determined using acoustic measurements from two microphones that were flush mounted near the reference plane where the orifice was placed (see Figure 1). The cross-spectra data from these signals were processed with an HP 3667A Signal Analyzer and then used in the Chung and Blaser² algorithm for the Two Microphone Method processed on a Pentium II platform. A sinusoidal input from a function generator was supplied to the JBL acoustic driver via a Carvin Amplifier. The amplitude of the discrete tone was fixed at constant incident sound pressure levels prescribed in Table I. The incident amplitude was extracted from the measured impedance via the method outlined in Chung and Blaser². It took several iterations before finding the correct driver voltage that produced the correct incident sound pressure level, but once found, the voltage was matched for all subsequent runs to produce a given amplitude of incident sound. Data from the microphones were analyzed from 0 – 6400 Hz with a bandwidth of 4 Hz and 64 averages.

4.0 Results

4.1 Incident Sound Pressure Level Spectra

Sound pressure level (SPL) as a function of spectra were obtained and are provided in Appendix A for use in computational models. Figure 4a and 4b show typical spectra of incident SPL for a 3000 Hz input signal for nominal amplitudes of 130 dB and 150 dB, respectively. Note that for both of these amplitudes, relatively strong harmonics exist. However, the first harmonic for the 150 dB case is almost 20 dB lower than the fundamental. For comparison purposes, the acoustic impedance was measured for an incident broadband noise signal of an average value of about 85 dB at all frequencies up to 6 kHz. Figure 5 shows the incident broadband noise spectrum for this case. The impedance resulting from this broadband incident spectrum can be considered the "linear" response of the slit-orifice-cavity.

4.2 Absorption Coefficient Data

The absorption coefficient was calculated from the measured reflection coefficient using the relationship:

$$\alpha = 1 - |R|^2 \quad (1)$$

where the complex Reflection coefficient, R , is expressed as a function of the complex normalized impedance, Z , as:

$$R = \frac{z - 1}{z + 1} \quad (2)$$

Figure 6 shows the absorption coefficient for the slit-orifice with backing cavity as a function of frequency and two magnitudes of incident sinusoidal tones: 130 and 150 dB. For comparison, the absorption coefficient for the low level incident broadband noise signal is also included. Note that the broadband data shows a relative peak absorption near 1086 Hz, with another peak near 6200 Hz. The latter peak corresponds to the anti-resonance condition where the reactance and resistance are near optimal for absorption. The peak at 1086 Hz corresponds approximately to the Helmholtz resonator frequency. Following Ingard's formulation⁴ for the end correction of a rectangular orifice, the approximate end correction to be applied for the slit orifice is

$$\delta_{end} = 0.4\sqrt{A_o} \quad (3)$$

which is less than half of its value for a circular orifice in an infinite plane. Thus, using this modified end correction and the appropriate values of orifice area and cavity volume in the classical Helmholtz equation yields a resonance frequency of 1102 Hz. This agrees remarkably well with the measured peak absorption of 1086 Hz.

Figure 6 also shows that the absorption in the vicinity of the Helmholtz resonance frequency increases significantly with increased incident SPL as evidenced by the 130 dB and 150 dB tone results. This is an indication of the nonlinear behavior of the slit-orifice. The fact that the 130 dB data has a higher absorption coefficient than the 150 dB data in the resonance region (~ 1100 Hz) may be due to better impedance matching at 130 dB.

4.3 Reflection Coefficient and Impedance Data

Figure 7 shows the reflection coefficient data for the broadband, 130 dB and 150 dB incident level cases. Both magnitude and phase are presented. The magnitude of the reflection coefficient follow trends exhibited by the absorption coefficient due to the relationship defined in equation 1. Figure 8 shows the corresponding impedance, both resistance and reactance are presented. The increased resistance as the incident SPL is increased (see Figure 8a) demonstrates the nonlinear nature of the slit-orifice under increasing incident sound energy. The frequencies at which the normalized reactance vanishes (see Figure 8b) correspond to the peak absorption frequencies of Figure 6.

4.4 Flow Visualization

Visualization of the acoustic interaction of the slit-orifice with backing cavity was performed with a PIV apparatus described in Section 2. Figure 9 shows some typical flow patterns of a relatively low and high incident SPLs occurring near the slit-orifice and in the backing cavity. At the lower incident levels (Figure 9a), flow circulation patterns are visible that correspond to patterns that Ingard and Labate⁵ first documented many years ago. The incident sound pressure levels in Figure 9a correspond approximately to levels that exist for a broadband signal. At high

incident levels (Figure 9b) clear indications of vortical motion is present, which is indicative of high fluctuating velocity in the orifice, thus producing vorticity formation at the orifice edges.

Figure 10 shows an instantaneous snapshot of the slit-orifice exposed to an incident sinusoidal acoustic wave of 1000 Hz at 130 dB and 150 dB. It is clear that even at 130 dB, there is a strong vortix that is convecting away from the orifice. A similar vortex can be seen at 150 dB. This suggests that strong acoustic absorption in the form of conversion of acoustic energy into vortical energy is present at these conditions as quantitatively shown in Figure 6.

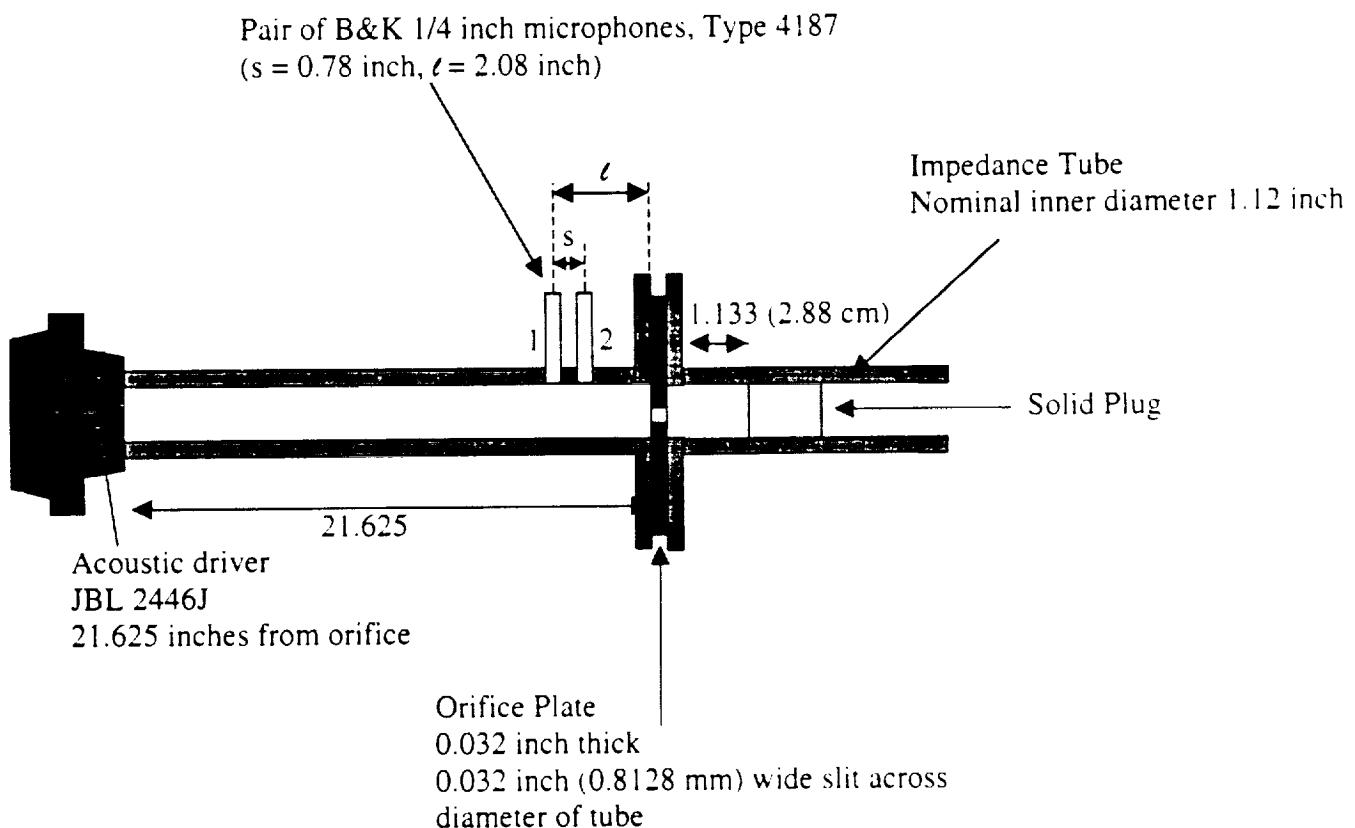

Figure 11 shows an instantaneous snapshot of the slit-orifice exposed to a incident sound wave of 3000 Hz at 130 dB and 150 dB. Note that at 130 dB, the flow patterns look similar to those observed in Figure 9a, i.e., for low incident SPL. This would suggest that not a lot of absorption is taking place via vorticity formation relative to 130 dB at 1000 Hz. This can be shown by comparing Figure 10 and Figure 11 at the 130 dB conditions. Note that the 1000 Hz flow pattern clearly shows a strong vortex at 130 dB while none is present at 3000 Hz. The absorption coefficient data of Figure 6 confirms this. Furthermore, at 3000 Hz and 150 dB, a vortex is present, again suggesting an increase in acoustic absorption. This is also shown in the absorption coefficient data when comparing the 130 dB and 150 dB cases at 3000 Hz.

5.0 Concluding Comments

Note that the purpose of acquiring the data presented here was to provide it to Dr. Tam for validating the numerical model of sound absorption by a narrow rectangular slit orifice with a backing cavity, being developed by him. The data has been provided to him and NASA Langley Technical monitor for use by others. We understand that Dr. Tams model predicts most of our findings. A joint paper will be presented in a future conference to discuss this comparison.
